# Replacing Oracle with Postgres: How to Successfully Migrate Your Legacy Databases

This white paper focuses on the most popular source and target for database migrations: moving from Oracle to Postgres. Oracle's pricing and licensing policies are driving organizations to look for other database solutions.

Postgres is the logical target for the migrations. With a constant stream of innovations reflected in annual releases, Postgres has achieved major database-of-the-year awards from [DBEngines.com](https://dbengines.com) and recognition as the #1 database in [StackOverflow's annual developer survey](https://stackoverflow.com/surveys). Not only is it clear that Postgres is winning the hearts and minds of innovation drivers, but its small footprint makes it an ideal solution in containers, too ([see Datadog survey](https://www.datadog.com/)).

The principles and approaches described in this paper are applicable to other source/target combinations, as well.

## You'll find:

- A quick review of the business drivers and migration approaches
- A dive into the migration journey and its challenges
- The best tools to get off Oracle quickly
- How to start taking advantage of Postgres' innovation, agility, and cost effectiveness

## Why is legacy database migration such a hot topic?

Traditionally, database license cost was listed as the primary reason driving organizations away from legacy databases—such as IBM's DB2, Microsoft's SQL Server, and Oracle—to open source databases, such as Postgres. [Gartner](#) market analysis notes continued adoption of open source solutions, such as Postgres.

While replacing Oracle with Postgres can yield cost reductions of upward of [80%](#), agility, innovation, microservices, and the move to the cloud have recently emerged as the dominant drivers.

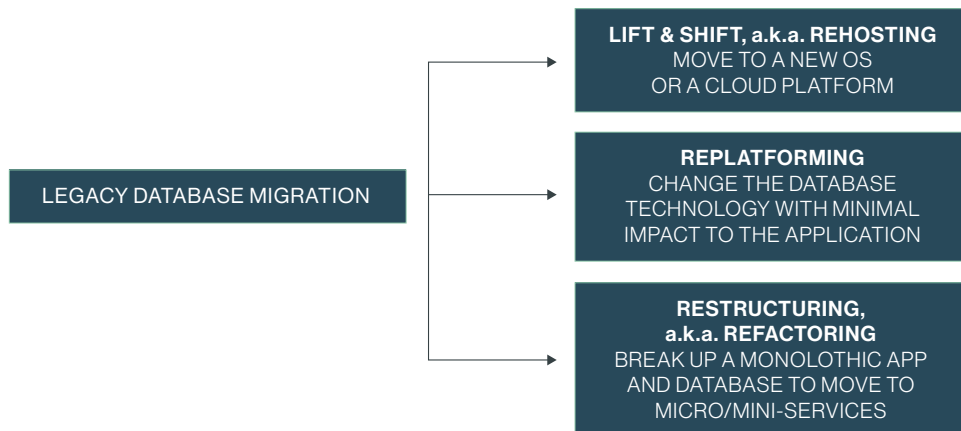

The growth of microservices, rather than monolithic databases, has become a key incentive for the move away from legacy databases. Because monoliths typically support many applications, it's difficult, if not impossible, to deploy changes and adjust scaling for individual services.

From an IT leadership perspective, we see license constraints and the desire to move away from proprietary data centers as two major drivers. Onerous legacy licenses drive cost up while constraining innovation and agility. For example, not every license is portable to every virtualization platform, every cloud, or every operating system—without even talking about scaling up and scaling down.

## Different types of database migrations

Legacy database migrations come in several forms:

- Lift and shift
- Replatforming
- Restructuring

The term "lift and shift" or rehosting is typically used to describe the move to a new host platform, but without changing the underlying software stack. For example, one can lift and shift an existing application that uses an Oracle database on Linux in the data center to a cloud IaaS, or a PaaS service that supports a managed version of the Oracle database.

Replatforming refers to a migration that exchanges the underlying database platform, with minimal or no changes to the application. For example, a migration of an application that uses an Oracle database to the Oracle-compatible [EDB Postgres Advanced Server](#) database is considered replatforming, as the application typically does not need to be modified.

Restructuring or refactoring is a more radical approach, where a monolithic legacy application is transformed into multiple smaller applications, which often impacts the backend database. The database can be broken up, or equipped with services interfaces to support a more modular application architecture. The restructuring approach is typically taken during microservices transformations that result in container and Kubernetes based architectures.

Migration	Pros	Cons	When Considered
<b>Lift and shift</b>	<ul style="list-style-type: none"> <li>Fast, easy, limited technology risk</li> <li>Easy way to move from the data center to the cloud</li> <li>No changes to the application or the database</li> </ul>	<ul style="list-style-type: none"> <li>Does not resolve legacy license issues or reduce license cost</li> <li>Does not improve agility or innovation</li> </ul>	<ul style="list-style-type: none"> <li>End-of-life applications that need to move out of the data center</li> <li>The move out of the datacenter is more pressing than the need to innovate or reduce software cost</li> </ul>
<b>Replatforming</b>	<ul style="list-style-type: none"> <li>Easy way to reduce database license cost and eliminate platform restrictions</li> <li>Minimal changes to the application and existing integrations</li> <li>Take advantage of Postgres innovation</li> </ul>	<ul style="list-style-type: none"> <li>May require minor application changes and retesting</li> </ul>	<ul style="list-style-type: none"> <li>High license cost databases with longer-term strategic role</li> <li>Use of database logic (stored procedures, packages) or proprietary features</li> </ul>
<b>Restructuring</b>	<ul style="list-style-type: none"> <li>Move to open source platform</li> <li>Highest degree of agility</li> <li>Supports move to K8s and containers</li> </ul>	<ul style="list-style-type: none"> <li>Significantly longer migration cycle with higher technology risk</li> </ul>	<ul style="list-style-type: none"> <li>Applications that are part of larger scale digital transformation with a business case supporting extensive redesign</li> </ul>

## Migration techniques and technologies

### A database migration from legacy to open source includes:

- Transforming the schema from a proprietary vendor's extended version of the SQL standard to a version more compliant with standards
- Rewriting data type definitions
- Rewriting queries and stored procedures
- Copying data
- Updating application APIs to use open source JDBC, .NET, ODBC, as most vendors have extended the standard protocols with proprietary extensions
- Verifying that the migrated database meets all the non-functional requirements related to performance, manageability, high availability, and integration with enterprise security requirements

Executing these transformations manually can be a very daunting task. Except for very small databases without any business logic and extremely simple application logic, we would not recommend this approach. It is too expensive and too error-prone.

### That is why two automated approaches are well established today:

The **translation approach** uses automated tools to rewrite (or translate) the definitions, queries, and stored procedures from the proprietary database to the open source database. The translation approach is used by [AWS's Schema Conversion Tool \(SCT\)](#), [Ispirer's MnMTK](#), and the open source tool [ORA2PG](#).

The **native compatibility approach** extends the open source databases' capabilities and creates a native implementation of the proprietary vendor's extensions of the SQL standard, including the APIs and protocols. For example, EDB's Postgres Advanced Server has a native implementation for Oracle's procedural SQL language PL/SQL, which includes packages and Oracle's proprietary driver extensions to ODBC, JDBC, .NET, and OCI. This allows code that was written for the Oracle database to run directly on EDB Postgres Advanced Server with minimal changes. The native implementation approach is used by EDB as part of EDB Postgres Advanced Server to achieve compatibility with the Oracle database. The open source tool [ORAFCE](#) also attempts to provide some level of compatibility with Oracle, although not to the same degree as the EDB solution.

Approach	Pros	Cons	When Considered
<b>Manual Transformation</b>	<ul style="list-style-type: none"> <li>Targets open source Postgres</li> </ul>	<ul style="list-style-type: none"> <li>Significant effort required</li> <li>Significant risk of error</li> </ul>	<ul style="list-style-type: none"> <li>Very small, non-mission critical databases</li> </ul>
<b>Translation</b>	<ul style="list-style-type: none"> <li>Targets open source Postgres</li> </ul>	<ul style="list-style-type: none"> <li>Limited ability to accommodate all proprietary capabilities</li> <li>Potentially requires significant database logic rewrites</li> <li>Often requires application modification as nonstandard/proprietary APIs and SQL may not be supported in Postgres</li> </ul>	<ul style="list-style-type: none"> <li>Simple databases using only standard SQL queries.</li> <li>Databases and applications that do not use stored procedures, packages, or proprietary data types</li> <li>Application interfaces limited to standard APIs</li> </ul>
<b>Native Compatibility</b>	<ul style="list-style-type: none"> <li>Migrates majority of proprietary capabilities (&gt; 90%)</li> <li>Minimal application rewrites</li> </ul>	<ul style="list-style-type: none"> <li>Targets proprietary version of Postgres (EDB Postgres Advanced Server)</li> </ul>	<ul style="list-style-type: none"> <li>Databases with business logic (stored procedures, packages, queries)</li> <li>Databases targeted by Oracle DBLink</li> </ul>

## Comparing the migration techniques

Take for example one of our large media customers: The company migrated its Oracle database containing 10,938 database objects (tables, stored procedures, packages, etc.) in 35 person days, including data transfer and testing, as 91% of all the objects were supported by EDB's native compatibility. Only two packages, which included approximately 9% of the code, needed to be rearchitected for compatibility with EDB Postgres Advanced Server.

In the same application, only the storage objects (tables and views) and some functions were open source Postgres compatible using the translation approach with ORA2PG. The rearchitecting approach for 65% of the code was estimated to be between 1.5 and 2 person years of effort.

In another example, a telecom provider was migrating a database with 15 procedures and nine functions, all defined in one custom Oracle package. The logic made extensive use of DBMS\_LOB, DBMS\_SESSION, DBMS\_XMLGEN.convert(), and the PIPELINED table function.

This customer targeted a migration directly to open source Postgres that required reworking all the business logic in a migration project, which necessitated 35 person days of effort using the translation approach. Using EDB Postgres Advanced Server's native compatibility approach, this migration could have been executed in approximately three person days, with minimal impact to the application and with minimal retesting.

## Legacy database migrations and the cloud

Data center closures and migration to the cloud are key drivers for database migrations. When migrating databases to the cloud, the user is left with several options, even after deciding to move to Postgres:

- Private cloud, such as OpenShift, Nutanix, or VMware
- Public Cloud Infrastructure as a Service (IaaS), such as AWS EC2 or GCP
- Public Cloud Kubernetes Platforms, such as GKE, AKS, or EKS
- Public Cloud Database as a Service (DBaaS), such as RDS Postgres, Aurora I/O-Optimized, Azure Database for Postgres, Google's Cloud SQL for Postgres, or [EDB Postgres AI Cloud Service](#)

While they all implement the Postgres API, there are key differences in migration capabilities. EDB's native compatibility with Oracle is available on OpenShift, VMware and all IaaS and K8s platforms, as well as on EDB Postgres AI Cloud Service. RDS, Aurora, Azure Database for Postgres, Google's Cloud SQL for Postgres are limited to the translation approach.

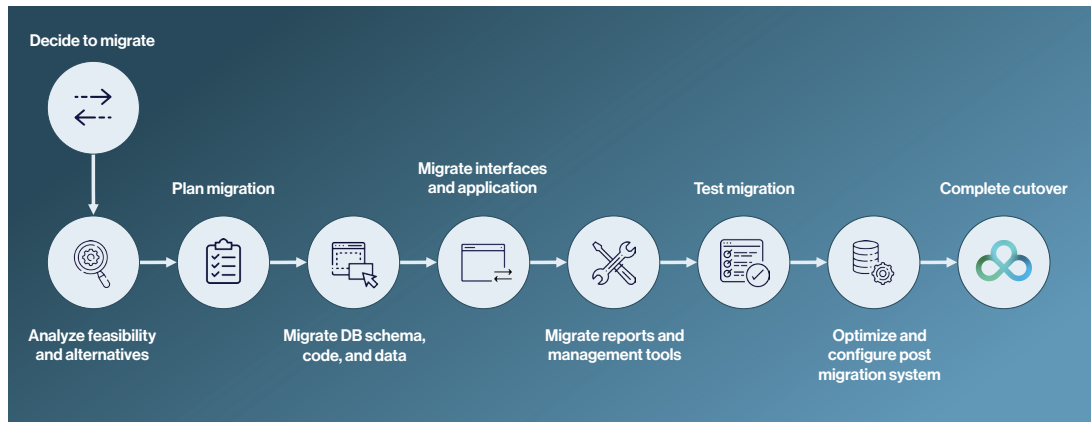

From a non-functional perspective, IaaS, VMware, OpenShift, and K8s platforms provide the highest level of control for performance, manageability, and integration – but they also require in-house deployment and management resources. Leading DBaaS platforms address these issues, but they limit configurability for non-functional requirements.

[Data gravity](#) makes it extremely important to think about the target platform early in the process. Even if you start a migration project with a simple database that is well served with the translation approach to migration, a later stage application may require capabilities that are only available as part of the native compatibility approach, such as legacy/proprietary database APIs or database links from other Oracle databases.

The same is true when selecting the cloud platform. Initial migrations may be served well by a DBaaS provided by a cloud service provider, such as AWS, Microsoft Azure, or Google Cloud, for whom Postgres is just another software platform that they operate. More advanced applications may need greater access to tuning parameters, as is provided on IaaS platforms, or the services of a Postgres specialist such as EDB.

# The nine steps of the migration journey

EDB has been migrating databases for more than 20 years. While most of our migrations have been from Oracle or SQL Server to Postgres, we have also executed major migrations from DB2.

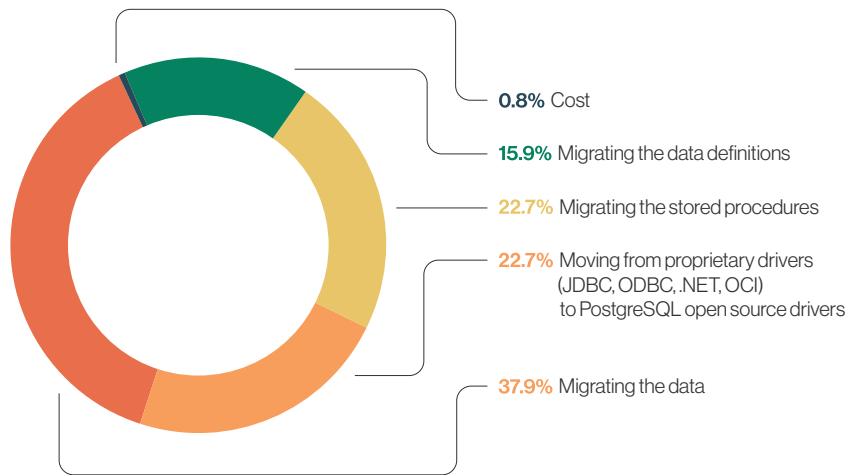

Experience shows that the enterprise migration journey follows nine steps:

Step	Focus	Outcome
<b>Decide to migrate</b>	<ul style="list-style-type: none"> <li>Business case</li> <li>Business priority</li> </ul>	<ul style="list-style-type: none"> <li>Decision to undertake migration at scale</li> <li>Get off legacy databases</li> </ul>
<b>Analyze feasibility and alternatives</b>	<ul style="list-style-type: none"> <li>Review the application portfolio</li> <li>Align the migration with the IT strategy and priorities</li> <li>Decide if we go to public cloud</li> </ul>	<ul style="list-style-type: none"> <li>Large scale plan to migrate</li> <li>Migration targets: which cloud, which database (open source/closed source)?</li> <li>Organizational alignment</li> </ul>
<b>Plan migration</b>	<ul style="list-style-type: none"> <li>Prioritize applications</li> <li>Lift &amp; shift, replatforming, or restructuring?</li> <li>Define non-functional requirements</li> <li>High-level solution design</li> <li>Estimate effort</li> </ul>	<ul style="list-style-type: none"> <li>Prioritized list of applications and databases, each identified as lift &amp; shift, replatform, restructure, or leave behind</li> <li>Performance, HA, and management integration requirements</li> <li>Migration architecture and high-level post-migration architecture</li> <li>High-level effort estimate, skills requirements, and staffing plan</li> </ul>
<b>Migrate database, code, and data</b>	<ul style="list-style-type: none"> <li>Move schema</li> <li>Migrate database functionality</li> <li>Migrate data as snapshot and/ or CDC</li> </ul>	<ul style="list-style-type: none"> <li>Functional database with all or some of the data</li> <li>Clear understanding of the need for CDC and migration cutover timelines</li> <li>Valid proof of concept that definitions, code, and data can be migrated</li> <li>Understanding of any gaps and effort assessment to close the gaps</li> </ul>
<b>Migrate interfaces and application</b>	<ul style="list-style-type: none"> <li>Migrate APIs (JDBC, ODBC, OCI, .NET, ...)</li> <li>Convert embedded application SQL</li> <li>Migrate applications</li> </ul>	<ul style="list-style-type: none"> <li>Running application that meets functional requirements</li> <li>App and database are integrated</li> </ul>
<b>Migrate reports and management tools</b>	<ul style="list-style-type: none"> <li>Migrate reports</li> <li>DBA utilities and script</li> </ul>	<ul style="list-style-type: none"> <li>DBA tools (data loading and other management) are functional</li> <li>Reports generated through SQLPlus or other means, e.g., Tableau, Qlik</li> </ul>
<b>Test migration</b>	<ul style="list-style-type: none"> <li>Data validation</li> <li>Functional validation</li> <li>Performance validation</li> </ul>	<ul style="list-style-type: none"> <li>Proof that the data migration is working correctly</li> <li>Proof that the code and the APIs are working correctly</li> <li>Proof that migrated database and code meet performance requirements</li> </ul>
<b>Optimize and configure post migration</b>	<ul style="list-style-type: none"> <li>Database tuning</li> <li>Query tuning</li> <li>Application tuning</li> <li>Address HA, DR, security, authentication/ authorization reqs</li> </ul>	<ul style="list-style-type: none"> <li>Updated indexing strategy</li> <li>Validation of non-functional requirements</li> <li>SOP (Standard Operating Procedures) and DevOps automation</li> </ul>
<b>Complete cutover</b>	<ul style="list-style-type: none"> <li>Completion of CDC</li> <li>Rollback setup</li> <li>Go/No-Go</li> <li>Production cutover</li> </ul>	<ul style="list-style-type: none"> <li>Completed migration</li> </ul>

## What makes Oracle migrations difficult?

A survey of 1,500 respondents from the EDB Postgres downloads page shows that data definitions are usually easy to migrate, but stored procedures, APIs, and the data are increasingly difficult. While migrating data may initially appear easy, mapping of data types can be challenging, and the incremental data migration—a.k.a. change data capture (CDC) that is required for larger databases—can be impossible without the right tooling.

Almost a quarter of the respondents mentioned that migrating from Oracle's proprietary drivers to open source Postgres was the second most difficult thing to do. This is because:

- There is no open source equivalent for Oracle's OCI driver or for Oracle's Pro\*C interface
- The "standard" drivers (JDBC, ODBC, .Net) have been heavily extended to support calling stored procedures, in/out parameters, and cursors.

Replacing the proprietary drivers with their nearest open source brethren implies significant modifications in the application logic.

Business logic, mostly stored procedures, is generally seen as a major migration obstacle during manual migrations or when one uses the translation approach. EDB's migration portal is a public website that allows anybody to assess their Oracle DDL for migratability to EDB Postgres Advanced Server. Since January 2019, we have analyzed over 18 million DDL constructs (CREATE TABLE, CREATE STORED PROCEDURE, etc.) for our customers and helped them migrate to EDB Postgres Advanced Server.

### This analysis reveals important data that should influence a migration plan:

- 14% of all schemas had at least one reference to PRAGMA AUTONOMOUS\_TRANSACTION
- 14% of all schemas had at least one HINT
- 32% of all schemas referred to at least one of the EDB supported Oracle packages, with DBMS\_OUTPUT, DBMS\_SQL, DBMS\_UTILITY, and DBMS\_LOB representing the majority of those packages

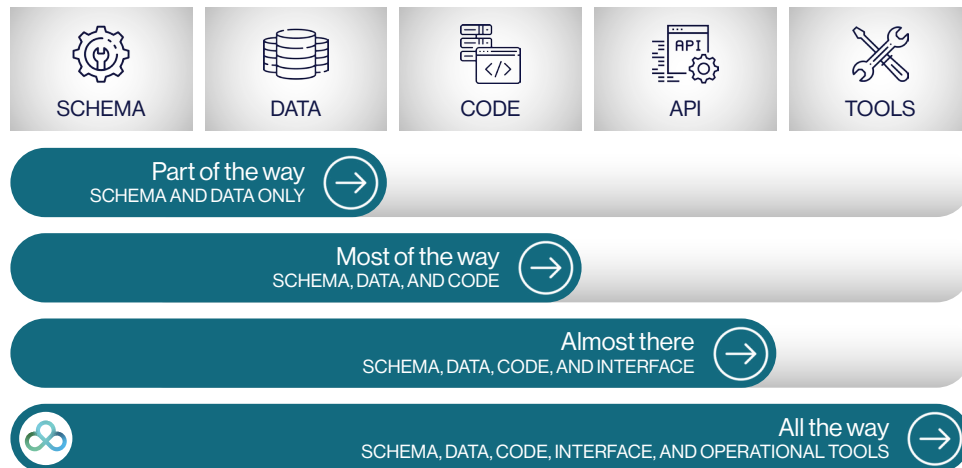

## What EDB brings to the table

Some of these elements, such as PRAGMA\_AUTONOMOUS\_TRANSACTION or HINT, are virtually impossible to reproduce in Postgres, which means that a translation approach will require extensive rewrites.

EDB has enabled legacy database migrations for 20+ years. We have assembled a systematic set of tools to make migration easier, predictable, and risk free. We have chosen the native compatibility approach, and we have learned that successful migrations are not limited to the data and stored procedures, but that a complete business solution requires the APIs and operational tools.

## Oracle Database Migration Solutions

- EDB Postgres Advanced Server is at the heart of our approach. EPAS is an Oracle Database compatible distribution of Postgres that natively understands PL/SQL, packages, Oracle-specific data types, DBA specific views etc.
- EDB provides Oracle-compatible JDBC, ODBC, .NET, OCI and Pro\*C drivers for the database
- The EDB Migration Portal is a website that allows users to upload Oracle database DDL definitions, and migrate them to EDB Postgres Advanced Server by leveraging its native compatibility, rewrite rules, and well-defined work arounds
- Our [EDB Migration AI Copilot](#) advances self-service migrations with an EDB AI-driven chat interface.
- EDB Replication Server is used for incremental data migration, a.k.a. Change Data Capture, which is key when migrating larger data sets (>100 GB) without significant downtime.
- LiveCompare makes it easy to validate the consistency of a migrated data set
- Management and high-availability tools that vary based on the indexing technique employed

## EDB Postgres Advanced Server: The heart of the native compatibility approach

EDB Postgres Advanced Server provides robust Oracle compatibility—on premises or in the cloud. As a result, you can modernize legacy systems and re- platform existing applications to deploy modern solutions for transactional, analytical, and AI workloads. Equally important: EDB Postgres Advanced Server provides flexible, extensible open source PostgreSQL functionality combined with capabilities familiar to Oracle users—advanced replication, high availability, security, and performance diagnostics.

With EDB Postgres Advanced Server, you can migrate your database to where your business needs it, with deployment options that include:

- On-premises on physical servers, virtual machines, Kubernetes/containers, or private cloud
- Kubernetes/containers
- Public cloud—fully managed EDB Postgres AI Cloud Service running on AWS, Google Cloud, and Microsoft Azure, as well as self-managed

The compatibility features built into [EDB Postgres Advanced Server](#) enable you to migrate your database in less than 20 days and reduce application rewrites by 95%. More schema, SQL, and code can run in Postgres without modification, which means that less schema, SQL, and code needs to be converted or rewritten. The compatibility features also allow DBAs and developers to work with familiar database schema and code constructs and syntax.

EDB Postgres Advanced Server not only eases the transition to Postgres from Oracle by providing users with familiar interfaces, they also allow many existing database management and reporting scripts that have been built to continue to be used with little or no modifications.

### Natively compatible database drivers

Natively compatible database drivers are the second key piece in migrations that minimize the impact on applications. EDB provides Oracle database compatible JDBC, ODBC, .NET and OCI drivers

Oracle Compatibility Feature	JDBC	ODBC	.NET	OCI
PL/SQL Support	✓	✓	✓	✓
REF_CURSOR - enhanced support	✓	✓	✓	✓
User-defined Exceptions - vendor code	✓	✓		✓
Named Parameters - parameter names	✓	✓	✓	✓
Data Types- VARCHAR2, STRUCT, ARRAYS	✓	✓	✓	✓
STRUCT - Enhanced Manipulation	✓		✓	✓
Multiple INOUT/OUT parameters	✓	✓	✓	✓

## EDB Migration Portal: Quick and easy migration of schemas and business logic

The EDB Migration Portal (<https://migration.enterprisedb.com>) is a graphical tool that analyzes Oracle schemas for compatibility, applies transformation rules and workarounds, and then loads the migrated schema into EDB Postgres Advanced Server on premises, on IaaS, on K8s, or on EDB Postgres AI Cloud Service..

The screenshot displays the EDB Migration Portal interface. The main area shows a migration progress report for the HRPLUS schema. The report indicates that 63 total objects were processed, with 95% passed, 3 failed, 41 system repaired, 0 user repaired, and 19 passed. A table lists the following object types and their counts:

Object Type	Count	Progress
Sequences	3	100%
Types	1	100%
Tables	11	100%
Constraints	10	100%
Procedures	9	100%
Functions	4	100%
Packages	1	100%
Package Body	1	100%
Indexes	11	100%
Views	9	96%
Triggers	3	100%

An AI Copilot chat window is open on the right, providing a PostgreSQL-compatible version of an Oracle SELECT statement:

```

CREATE a PostgreSQL version of this Oracle statement: "SELECT COLUMN_VALUE FROM SYS.ODCIVARCHARLIST('a','b','c');"
SELECT UNNEST(ARRAY('a','b','c')) AS COLUMN_VALUE;
    
```

EDB Migration Portal now includes the EDB Migration Copilot, which leverages AI to enable customers to complete migration-related tasks in a self-service model, with instant error resolution

The screenshot displays the EDB Migration Portal Portal Wiki page for ERH-2035 BINARY\_FLOAT\_DATATYPE. The page provides a description, example SQL code, and implications for migration.

**ERH-2035 BINARY\_FLOAT\_DATATYPE**

**Description**

Transforms BINARY\_FLOAT to REAL. EDB Postgres Advanced Server does not support BINARY\_FLOAT datatype.

**Example**

```

CREATE TABLE tob2(
  a BINARY_FLOAT
);
    
```

**Target**

```

CREATE TABLE tob2(
  a REAL
);
    
```

**Implications**

In Oracle, a BINARY\_FLOAT data type can store values as small as 1E-38 and as big as 3E+38. On the other hand, in EDB Postgres Advanced Server, the REAL type has a range of at least 1E-37 to 1E+37. This can impact data migration.

EDB Migration Portal Repair Handlers are used to fix a set of known incompatibilities and report the results

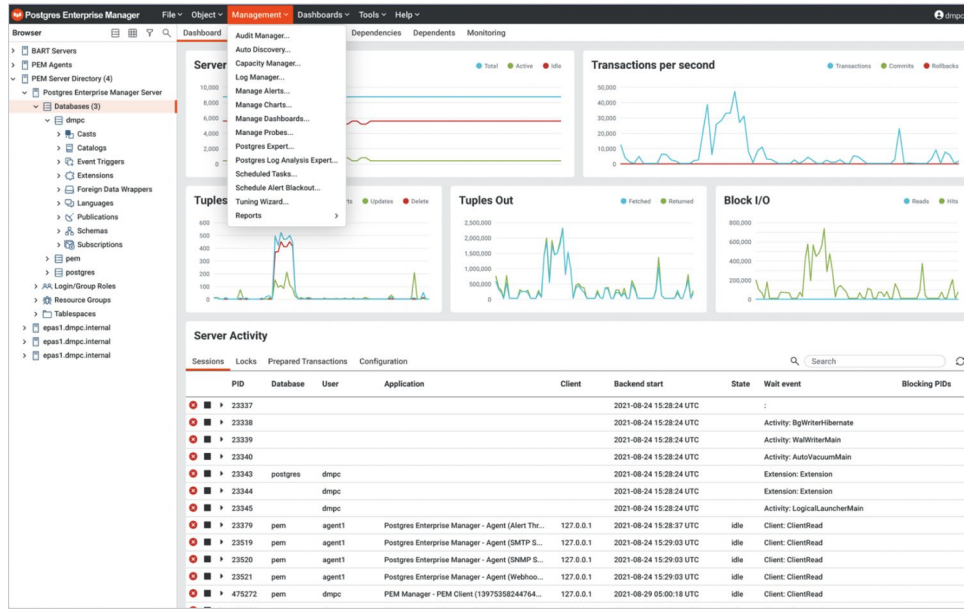

## Operational tools for management and high availability

It is important to remember that migration is not just about migrating definitions, code, and data. To make the migrated database a successful business solution, it needs to be operated with the same reliability and efficiency as the legacy solution.

EDB provides an array of management and high availability tools to make sure that non-functional requirements, such as management at scale, minimal downtime, and RPO/RTO/GRO are met effectively.

Postgres Enterprise Manager provides a GUI-based tool for managing Postgres installation at large scale, using dashboards, alerts, and analysis tools.

Postgres Enterprise Manager keeps databases running smoothly, continuously monitoring database and server health with real-time graphical dashboards and automatic alerts

[EDB Postgres Distributed](#) supports deployment of robust, globally distributed applications that process thousands of transactions per second, with up to 99.999% availability. Running EDB Postgres Distributed on EDB Postgres AI Cloud Service supports high availability active/active geo-distributed deployments, with up to 99.995% availability.

EDB's Failover Manager enables high availability of primary-standby deployment architectures using streaming replication. Failover Manager provides a Postgres primary database node automatic failover to a standby database node in the event of a software or hardware failure. You can use Failover Manager with PostgreSQL or EDB Postgres Advanced Server.

Barman (Backup and Recovery Manager) is a Postgres backup tool and an open source project with contributors from around the globe. Now managed by EDB, Barman provides enterprise-level features, including multi-server backup, backup compression, and comprehensive reporting, make it a valuable tool for managing Postgres backups efficiently.

## EDB Professional Services and Support for Oracle modernization

EDB Postgres subject matter experts help ensure a smooth transition by providing consulting services to assist customers requiring assistance with complex migrations and those requiring resources to supplement technical staff. Professional Services has a global team of subject matter experts that can support every component of migrations. Professional Services also offers expertise via the Migration Factory, which allows for expedited assessments, and rapid conversion of schema for cost and time optimized migrations. With a full range of packages, custom statement of works, and options for ongoing expertise, EDB Professional Services meets all your deployment needs.

## Getting started

After deciding to get off of legacy platforms, the first question is: *Where do we start?* Years of experience have helped us identify key criteria to select applications that are a good starting point for a large scale migration.

### **Applications that meet the following criteria tend to be prime candidates to prioritize in a large scale migration project:**

- Use of an object-relational mapping tool (ORM), such as Hibernate or Spring
- Procedures, functions, packages, and triggers written in PL/SQL, and not in Java
- While we don't expect significant application changes, migrations may require the ability to modify source code, or at least analyze it to architect a suitable workaround
- No use of RAC for scalability
- No need for Flashback
- A test harness to validate functional and non-functional requirements after the migration is generally helpful

### **A second tier of slightly more involved migrations are often characterized by:**

- OCI interface
- Oracle Spatial and XML
- Oracle-specific extensions of .NET and ODBC that are not covered by EDB's drivers

### **Applications that meet these criteria should only be tackled after the migration team has gained significant experience or when working in close collaboration with a migration expert, such as EDB.**

- Pro\*C interface
- Transaction management control inside PL/SQL (Commit/rollback/ savepoint/exceptions)
- Stored procedures written in Java
- Must have RAC scalability capabilities and Flashback

These guidelines can be used to prioritize applications during the Migration Planning phase, before actually looking at the code and running the schema through the EDB Migration Portal.

EDB's experience shows that approximately 50% of all databases fall into the first category, and can be migrated easily, usually in 10–20 person days, including data transfer and verification. About 25–30% fall into the second category.

## Summary

Legacy database migrations, predominantly away from Oracle, are a major concern for enterprises striving for greater agility, cost reduction, and migration to the cloud. Postgres has been the dominant target, and when it is enhanced with native Oracle database compatibility, migrating becomes quick and easy. Other migration techniques that rely on manual transformations or on-the-fly translation approaches tend to involve a lot more risk, and are significantly more labor intensive.

EDB provides a proven methodology and a complete set of migration and operations tools to get you to Postgres quickly, and to make sure that you create a working and reliable business solution.

Download [EDB Postgres Advanced Server](#), or experience native Oracle database compatibility through [EDB Postgres AI Cloud Service](#), EDB's managed database as a service. Use your own examples to evaluate how well EDB's [Migration Portal](#) and EDB's [Migration Toolkit](#) help you migrate schema, data, and business logic.

### About EDB

EDB provides a data and AI platform that enables organizations to harness the full power of Postgres for transactional, analytical, and AI workloads across any cloud, anywhere. EDB empowers enterprises to control risk, manage costs and scale efficiently for a data and AI-led world. Serving more than 1,500 customers globally and as the leading contributor to the vibrant and fast-growing PostgreSQL community, EDB supports major government organizations, financial services, media and information technology companies. EDB's data-driven solutions enable customers to modernize legacy systems and break data silos while leveraging enterprise-grade open source technologies. EDB delivers the confidence of up to 99.999% high availability with mission-critical capabilities built in such as security, compliance controls, and observability. For more information, visit [www.enterprisedb.com](http://www.enterprisedb.com).
